ABSTRACT

Analyzing initiating event rates is important because it indicates performance among plants and also provides inputs to several U.S. Nuclear Regulatory Commission (NRC) risk-informed regulatory activities. This report presents an analysis of initiating event frequencies at U.S. commercial nuclear power plants from calendar year 1988 through 2015 as reported in licensee event reports. Engineers with nuclear power plant experience reviewed each event report since the last update to this report for the presence of valid scrams or reactor trips at power. To be included in the study, an event had to meet all of the following criteria: (1) the event includes an unplanned reactor trip (not a scheduled reactor trip on the daily operations schedule), (2) the sequence of events started when reactor is critical and at or above the point of adding heat, (3) the event occurred at a U.S. commercial nuclear power plant (excluding Fort St. Vrain and LaCrosse), and (4) the event was reported by a licensee event report.

Sixteen initiating event groupings are trended and displayed. For some of the categories as relevant initiators are plotted separately for boiling water reactors and pressurized water reactors. P-values are given for the possible presence of a trend over the most recent 10 years. No statistically significant trends were observed.

Initiating Event Rates at U.S. Nuclear Power Plants 1988–2015

1. INTRODUCTION

An initiating event is an unplanned event that occurs while a nuclear power plant is in critical operation and requires that plant to shut down to achieve a stable state. Analyzing initiating event rates is important because it indicates performance among plants and also provides inputs to several U.S. Nuclear Regulatory Commission (NRC) risk-informed regulatory activities (such as plant inspections of risk-important systems) and NRC staff technical reviews of proposed license amendments, including risk-informed applications. The objectives of the initiating event study are to

- Provide revised, historical frequencies for the occurrence of initiating events in U.S. nuclear power plants
- Review the operating data from an engineering perspective to determine trends and patterns of plant performance for specific plants, plant types [i.e., pressurized water reactor (PWR) or boiling water reactor (BWR)], and the industry.

This report presents an analysis of initiating event frequencies at U.S. commercial nuclear power plants. The evaluation is based on the operating experience from calendar years 1988 through 2015, as reported in licensee event reports (LERs). This is the latest update to [NUREG/CR-5750](#) (Poloski et al. 1999), updating data, frequency estimates, trends, and figures.

To determine initiating event rates, engineers with nuclear power plant experience reviewed each LER since the last update to this report for the presence of valid scrams or reactor trips at power. To be included in this study, an event had to meet all of the following criteria:

- Includes an unplanned reactor trip, which is defined as a non-scheduled reactor trip on the daily operations schedule
- Sequence of events starts when reactor is critical and at or above the point of adding heat
- The events occurs at a U.S. commercial nuclear power plant (excluding Fort St. Vrain and LaCrosse)
- Is reported in an LER.

Each reactor trip event was then reviewed for the following information:

- All occurrences of risk-significant events in the reactor trip sequence that could impact the ability to remove reactor decay heat. These are called functional impacts.
- The initiator or first event in the sequence of events that caused or led to the unplanned, automatic, or manual reactor trip. This condition is called the initial plant fault.
- The events are marked according to whether the trip was automatic or manual.
- For the purposes of this report, the functional impact data are reported and trended. Note that a single event may appear in more than one category. Initiating events with no specific functional impact are listed in the “General Transients” category.

1.1 Changes from Previous Years

Highlights of the changes this year include the following:

- Data from calendar years (CY) 1988 onward are used in all analysis. Three months of FY 1987 data have been dropped in favor of moving to a calendar year.
- Prediction limit period length (future year) values (Table 1) have been updated to reflect availability of operating plants as of the current update year.

2. BASELINE FREQUENCIES

For each of the initiating events categories, a baseline period during which the initiating event frequencies are approximately constant was identified. New baseline periods were adopted in the 2012 edition of this report (Wierman 2013). These same baseline periods are used again in the present report. All baseline periods end in 2010 but have different starting years, according to how long the frequencies appear to have been stable and how many years are necessary to achieve a reasonable sample size.

The maximum likelihood estimate (MLE) is plotted for each occurrence rate in each calendar year. The MLE is calculated as the total number of events divided by the total number of reactor critical years. For each baseline period, MLE is the total event count (summed over the calendar years in the baseline period), divided by the corresponding sum of reactor critical years. The plotted vertical limits in each year are simple 5th and 95th percent confidence bounds, based on assuming the events occur according to Poisson distributions in each year.

An industry gamma-distributed occurrence rate for each initiating event baseline period is presented in Table 1. A gamma distribution is sought based on plant-to-plant variability and computed using the Empirical Bayes method where possible. If the Empirical Bayes method fails, the population is assumed homogeneous, and the occurrence rate distribution is computed using a Jeffrey's noninformative prior.

Using the baseline period industry gamma distribution the prediction limits for the current year are computed from the predictive distribution (gamma-Poisson) that describes the number of events that would be expected in the update year based on the number of baseline period events, the occurrence time in the baseline period, and the exposure time in the update year.

The predictive bounds computed from the baseline period assume that the occurrences are following a constant rate for the baseline period and for future years. Comparing future data with those bounds helps to determine whether the data are changing.

Ideally a baseline period is a time period during which one believes conditions to be both stable (i.e., the event rates are not trending either up or down and appear to be homogeneous with respect to yearly variation) and representative of current industry conditions. The baseline periods for the sparse initiators are longer than would normally be desirable, 20 years or more in six cases, in an effort to include sufficiently many events during the baseline period. Rates based on experience in the 1980s and early 1990s are likely to be conservative, as plants made large strides in increasing uptime and decreasing unplanned shut down during that time. Also, for loss of offsite power (LOOP) events, the desired stability condition was not met (a formal test of homogeneity across years shows highly statistically significant differences among years.) No recent period during which the LOOP rate was constant is available.

Table 1 summarizes the updated baseline data. For each initiator frequency, the table lists the total number of events and reactor critical years^a, the representative industry gamma distributions, and the upper prediction limit^b associated with the current update year.

a. A reactor critical year (rcry) is 8760 hours of critical operation for one reactor.

b. The prediction limit is the smallest number of future events such that the probability of seeing future counts as large or larger than the selected number is less than or equal to 0.05. A full discussion can be found in NUREG/CR-6932, Section B.2.

3. TRENDS

Table 2 shows the current 10-year trends for the sixteen initiating event types being tracked. For each event type, a p-value for a test of the significance of the trend is included along with the most recent, the year event count, and a comparison with its prediction limit.

The plots that follow Table 2 show the event occurrence rate trends from the most recent 10 years. The baseline period mean and the current year prediction limit bounds are marked. The vertical bounds for each year's occurrence rate represent the ninety percent confidence bounds on the estimate. Tables of LERs associated with the events and tables of the plotted data are provided in Appendix A.

No statistically significant trends were identified.

a. This column indicates the method of obtaining the Gamma distribution. EB/yr indicates that the Empirical Bayes method was used and the yearly data are the source of the variability. EB/PL indicates that the Empirical Bayes method was used and the plant to plant data are the source of the variability. NI means that the non-informative prior was used to obtain a distribution (this generally means that the data were sparse or that there is no variability in the data).

b. The p-value is 0.02, which is statistically significant but not highly statistically significant. LOOP performance during operational periods varies widely from year to year and the events are often not independent. At this point, it is not feasible to obtain a baseline period that is homogeneous.

c. No test p-value is reported because there is only one event in the industry exposure time from 1988 to 2010.
