ABSTRACT

Analyzing initiating event rates is important because it indicates trends and patterns of plant performance and provides inputs to several U.S. Nuclear Regulatory Commission (NRC) risk-informed regulatory activities. This report presents an analysis of initiating event frequencies at U.S. commercial nuclear power plants from calendar year 1988 through 2020, as reported in licensee event reports. Engineers with nuclear power plant experience reviewed each event report since the last update to this report to categorize and characterize reactor trips. To be included in this study, an event had to meet all of the following criteria: (1) the event included an unplanned reactor trip (not a scheduled reactor trip on the daily operations schedule), (2) the sequence of events started when the reactor was critical and at or above the point of adding heat, (3) the event occurred at a U.S. commercial nuclear power plant (excluding Fort St. Vrain and LaCrosse), and (4) the event was reported by a licensee event report.

Sixteen initiating event groupings are trended and displayed. For some of the categories, relevant events are plotted separately for boiling-water reactors (BWR) and pressurized-water reactors (PWR). P-values are given for the possible presence of a trend over the most recent 10 years.

The following trends were identified for the most recent 10 years (2011–2020):

- Highly statistically significant decreasing trend was identified for Loss of Offsite Power (p-value = 0.001).
- Statistically significant decreasing trend was identified for PWR general transients (p-value = 0.021).

Initiating Event Rates at U.S. Nuclear Power Plants, 2020 Update

1. INTRODUCTION

An initiating event is an unplanned event that occurs while a nuclear power plant is in critical operation, requiring that plant to shut down to achieve a stable state. Analyzing initiating event rates is important because it indicates trends and patterns of plant performance and provides input to several U.S. Nuclear Regulatory Commission (NRC) risk-informed regulatory activities (such as plant inspections of risk-important systems). It also supports the NRC staff technical reviews of proposed license amendments, including risk-informed applications.

The objectives of the initiating event study are to:

- Provide revised, historical frequencies for the occurrence of initiating events in U.S. nuclear power plants
- Review the operating data from an engineering perspective to determine the trends and patterns of plant performance for specific plants, plant types (i.e., pressurized-water reactor [PWR] or boiling-water reactor [BWR]), and the industry.

This report presents an analysis of initiating event frequencies at U.S. commercial nuclear power plants. The evaluation is based on the operating experience from calendar years (CYs) 1988 through 2020, as reported in licensee event reports (LERs). This is the most recent update to [NUREG/CR-5750](#) (Poloski, Marksberry, Atwood, & Galyean, 1999), updating data, frequency estimates, trends, and figures.

To determine initiating event rates, engineers with nuclear power plant experience reviewed each LER since the last update to this report to categorize and characterize reactor trips. To be included in this study, an event had to meet all the following criteria:

- Sequence of events started when the reactor was critical and at or above the point of adding heat
- Included an unplanned reactor trip, which is defined as a nonscheduled reactor trip on the daily operations schedule
- The event occurred at a U.S. commercial nuclear power plant (excluding Fort St. Vrain and LaCrosse)
- Was reported in an LER.

Each unplanned reactor trip event was then reviewed for the following information:

- All occurrences of risk-significant events in the reactor trip sequence that could impact the ability to remove reactor decay heat. These are called functional impacts (FIs) that include events such as loss of offsite power, partial loss of component cooling water (CCW), stuck-open safety relief valve (SRV), and loss-of-coolant accident (LOCA).
- The initiator or first event in the sequence of events that caused or led to the automatic or manual reactor trip. This condition is called the initial plant fault (IPF). IPF could either be one of the FIs or be one of the general transients. General transients are a compilation of all reactor trip initiators that had no direct impact on mitigating systems ability to remove decay heat. General transients include events such as manual reactor trip, turbine trip, spurious reactor trip, loss of non-safety related bus, and partial loss of feedwater.
- The events are marked according to whether the trip was automatic or manual.

- For the purposes of this report, the FI data and the IPF general transients categories are reported and trended.
- For each reactor trip, the sequence of events occurring any time before and shortly after the reactor trip is examined. There are three situations: (1) for most reactor trips, the event sequence may have no FI events at all. Such reactor trips will appear only in the IPF general transients category. (2) One or more FI events may be identified in a single reactor trip event sequence, and one of the FI events causes or leads to reactor trip. In this case, the reactor trip event will appear in more than one FI category, with the first FI event being coded as the IPF. (3) One or more FI events are identified in a single reactor trip event sequence, but none of them causes or leads to reactor trip. The event will appear in one or more than one FI category, while the IPF will be "General Transients".
- Using FI data to estimate the initiating event frequency for FI categories is proper when the occurrence of a risk-significant event category (e.g., total loss of the main feedwater system or steam generator tube rupture) is not specifically modeled in PRA as a conditional failure.
- The order in which the functional impact events occur is not considered in this study.
- A reactor trip sequence may have multiple occurrences of functional impact events. However, the increase in values are well within the uncertainty intervals estimated in the analysis.

1.1 Changes from Previous Years

Highlights of the changes this year include the following:

- 46 new initiating events occurred in 2020 (see Table 1).
- The Initiating Events counts for the last three years have been updated (see Table 2).
- After peer reviews and new information became available, LER 3132017001 was reclassified from Loss of Offsite Power to Loss of Vital AC Bus.

Table 1. Number of initiating events that occurred in 2020.

Initiating Event	Number of New Events in 2020
Loss of Offsite Power ^a	2
Loss of Vital AC Bus ^a	0
Loss of Vital DC Bus	0
Very Small LOCA	0
Partial Loss of CCW	0
Loss of Feedwater	4
Partial Loss of Service Water	0
BWR Loss of Instrument Air	0
BWR Stuck-Open SRV	0
BWR Loss of Heat Sink	0

PWR Steam Generator Tube Rupture	3	3	3
PWR Stuck-Open SRV	2	2	2
PWR Loss of Heat Sink	116	118	119
PWR General Transients	1871	1899	1924
Total	3507	3559	3606^b
^a One LOOP event occurred on 2017-04-26 (LER 3132017001) was reclassified as Loss of Vital AC Bus.			
^b One BWR general transient event occurred on 2017-04-20 (LER 3212017001) was identified and added to the database this year, which is why Table 1 shows 14 new BWR general transient events and 46 total events in 2020 but this table shows an increase of 15 BWR general transient and 47 total events from 1988-2019 to 1988-2020.			

2. BASELINE INITIATING EVENT FREQUENCIES

For each initiating event, a baseline period during which the event frequencies are approximately constant was chosen. The goal in determining baseline periods is to find periods during which one believes conditions to be both stable (i.e., the event rates are not trending either up or down and appear to be homogeneous with respect to yearly variation) and representative of current industry conditions. Another purpose of a baseline period is to generate the prediction limits (PLs). To develop PLs, two steps are required. The first step is to establish a baseline period for each initiating event, during which the data can be regarded as approximately constant. The second step is to select an appropriate constant model for the data in the baseline period. The PL is based on the baseline and corresponds to a 95% probability that future data points will not exceed the PL. The last baseline periods were developed in the 2016 edition of this report, INL/EXT-17-42758 (Johnson & Schroeder, 2017), with the baseline period ending in 2015 (referred as “2015 update baseline period” later).^a All baseline periods ended in 2015 but have different starting years, according to how long the frequencies appear to have been stable and how many years are necessary to achieve a reasonable sample size.

This report developed new baseline periods with the period ending in 2020, with the following criteria and process:

- The periods are at least four years long so that there is sufficient data to characterize performance (Nuclear Regulatory Commission, 2006).
- The selected periods represent “current” performance with the data in the baseline periods to be relatively “flat” (i.e., without significant trends within the periods, as shown by the p-value^b for the statistical test of the significance of a slope), and the hypothesis of homogeneity between years is not rejected.
- For the ten “sparse” initiating events (less than 20 events have occurred since 1988, see Table 3), the starting years are not changed from the 2015 update baseline periods unless the above trend and homogeneity criteria can’t be met.
- For the other six “not sparse” initiating events, various periods, including a ten-year period and a fifteen-year period, are investigated. The period that meets the above trend and homogeneity criteria will be chosen as the baseline period. This is different from the approach in the 2015 initiating event baseline analysis, which retained the length of the original baseline periods in NUREG/CR-6928 (Eide, Wierman, Gentillon, Rasmuson, & Atwood, 2007) such as ten-year period for loss of feedwater, eight-year for PWR loss of condenser heat sink, and seven-year for BWR loss of condenser heat sink.

Table 3 presents the new baseline periods developed in this update (referred as “2020 update baseline period”), along with those in the 2015 update baseline period for comparison purpose.

^a The 2019 edition of this report, INL/EXT-20-59192 (Johnson & Ma, 2020), conducted the baseline analysis with the baseline period ending in 2019. However, the 2019 baseline analysis was later superseded by the 2020 baseline analysis in this report to be used in other studies such as component performance studies and parameter estimation updates.

^b Statistically significant is defined in terms of the ‘p-value.’ A p-value, or probability value, is a number describing how likely it is that your data would have occurred, under the assumption that the null hypothesis is correct. When p-value of less than or equal to 0.05 we reject the null hypothesis of no trend. By convention, we use the “Michelin Guide” scale: p-value < 0.05 (statistically significant), p-value < 0.01 (highly statistically significant), p-value < 0.001 (extremely statistically significant).

Table 3. 2020 update baseline periods.

Category	Initiating Event	2015 Update Baseline Period	2020 Update Baseline Period
Sparse	Loss of Vital AC Bus	1992–2015	1992–2020
	Loss of Vital DC Bus	1988–2015	1988–2020
	Very Small LOCA	1992–2015	1992–2020
	Partial Loss of CCW	1988–2015	1988–2020
	Partial Loss of Service Water	1988–2015	1988–2020
	BWR Loss of Instrument Air	1991–2015	1991–2020
	BWR Stuck-Open SRV	1994–2015	1994–2020
	PWR Loss of Instrument Air	1997–2015	1997–2020
	PWR Steam Generator Tube Rupture	1991–2015	1991–2020
	PWR Stuck-Open SRV	1988–2015	1988–2020
Not Sparse	Loss of Offsite Power	2009–2015	2009–2020
	Loss of Feedwater	2006–2015	2011–2020
	BWR Loss of Condenser Heat Sink	2009–2015	2009–2020
	BWR General Transients	2010–2015	2011–2020
	PWR Loss of Condenser Heat Sink	2008–2015	2006–2020
	PWR General Transients	2011–2015	2016–2020 ⁽¹⁾

- (1) For PWR general transients, there is a highly statistically significant decreasing trend over the 2011–2020 period, with a p-value of 0.0207. Different starting year such as 2006, 2011, etc. were investigated. 2015 is the first year that does not have a significant p-value (p-value = 0.09, slope = -0.033). The p-value for the 2016–2020 period is 0.86 and this period has a slope closer to zero (slope = -0.012). As such, 2016–2020 was selected as the baseline period for PWR general transients.

Table 4 summarizes the updated baseline data. For each initiating event, the table lists the total number of events and reactor critical years^c, the representative baseline period industry gamma distributions, and the upper prediction limit^d associated with the current update year.

For the event frequencies, we sought a gamma distribution based on plant-to-plant variability. It was computed using the Empirical Bayes (EB) method in NUREG/CR-6823 (Atwood, et al., 2002) where possible. If the Empirical Bayes method failed to find finite parameters that maximize the likelihood that the population was treated as homogeneous, the occurrence rate distribution was computed using a Jeffrey's noninformative (NI) prior.

The upper PL is the smallest number of future events such that the probability of seeing future counts that will not exceed the PL is 95%. The PLs are computed from the discrete predictive distribution (gamma-Poisson) that describes the number of events expected in that update year based on the number of baseline period events, the occurrence time in the baseline period, and the assumed exposure time in the update year. They assume that the occurrences are following a constant rate for the baseline period and for future years. Comparing future data with those PLs helps to determine whether the data are changing. Refer to Appendix B of NUREG/CR-6932 (Eide, Wierman, Gentillon, Rasmuson, & Atwood, 2007) for more details on the predictive distribution and the estimations of PL.

^c. A reactor critical year (rcry) is 8760 hours of critical operation for one reactor.

^d. The prediction limit is the smallest number of future events such that the probability of seeing future counts as large or larger than the selected number is less than or equal to 0.05. A full discussion can be found in NUREG/CR-6932 (Eide, Wierman, Gentillon, Rasmuson, & Atwood, 2007)

Table 5 compares the results in the new 2020 update baseline period and those in the 2015 update baseline period.

Table 4. Baseline initiating event periods, prediction limits, and frequencies.

^a For each initiating event, the homogeneity test compares the observed chi-square statistic with simulated chi-square statistics from samples for which the observed number of counts are randomly (homogeneously) allocated to the years in a baseline period in proportion to their reactor critical years. The p-value is the proportion of the samples having as large or larger chi-square statistics. Small p-values (≤ 0.05 , for example) show statistically significant differences between years. The test does not require a large number of events.

^b This column indicates the method of obtaining the gamma distribution. EB/PL indicates that the Empirical Bayes method was used, and the plant-to-plant data are the source of the variability. NI means that the Jeffery's noninformative prior was used to obtain a distribution (this generally means that the data were sparse or that there is little or no variability in the data).

^c The baseline 95% prediction rate is the 95% value of the predictive distribution (which is different from the Gamma distribution in the previous column) during the baseline period. The 95% prediction rate and the assumed/expected exposure time in reactor critical year are used to calculate the 95% prediction limit, which means there is a 0.05 probability that the prediction limit of event count will be reached or exceeded for a given year. NUREG/CR-6932 has more details on the predictive distribution and how the 95% PL is estimated.

Table 5. Comparison between results in 2020 update baseline periods and 2015 update baseline periods

Initiating Event	2015 Update Baseline Period					2020 Update Baseline Period

^a The 2018 edition of this report (INL/EXT-19-54513) has a typo in the mean value for the 2015 Update Baseline Period, 1.02E-3 instead of 1.02E-2.

^b The 2016 edition, as well as the following editions (2017 and 2018), of this report have incorrect number (235) and critical years (355.04) of BWR General Transients for the 2015 Update Baseline Period in their corresponding Table 1. The mean value in those reports, 5.80E-1, are correct though.

3. CURRENT INITIATING EVENT DATA AND TRENDS

Table 6 summarizes the initiating event data for the entire study period (1988–2020), the most recent 10 years (2011–2020), and the current update year (2020). Event counts and reactor critical years are given. For the current update year, the maximum likelihood estimate (MLE) is calculated as the total number of events divided by the total number of reactor critical years. A comparison of the observed event count and the prediction limits from Table 4 is also provided. For the most recent 10 years, Table 6 provides a p-value for a test of the significance of the trend for each initiating event.

The plots that follow Table 6 show the event occurrence rate in each calendar year, as well as the trends from the most recent 10 years. The vertical bounds for each year's occurrence rate in the plots are simple 5th and 95th percent confidence bounds, based on assuming the events occur according to Poisson distributions in each year. The baseline period means and 95% upper prediction limits are provided in the plots for reference.^e Tables of data and the LERs associated with the events and data are provided in Appendix A. An overview of the trending methods, glossary of terms, and abbreviations can be found in (Gentillion, 2012) on the Reactor Operational Experience Results and Databases web page (<https://nrcoe.inl.gov/>).

The following trends were identified for the most recent 10 years (2011–2020):

- A highly statistically significant decreasing trend was identified for Loss of Offsite Power (p-value = 0.001) and can be viewed in [Figure 1](#).
- A statistically significant decreasing trend was identified for PWR general transients (p-value = 0.021) and can be viewed in [Figure 16](#).

It should be noted that although the p-value for Loss of Vital DC Bus is 0.032 (see [Figure 3](#)) for the most recent 10 years (2011–2020), this is not regarded as a decreasing trend here as there have been only one event in the last 10 years.

^e. The 90% prediction limit intervals in the figures of previous versions of this report are replaced by the 95% upper prediction limits. The lines of 5% lower prediction limits are removed from the figure as they are often mixed with the x-axis and the upper prediction limits are of primary concern. The values of 5% prediction limits are still provided in the appendix tables.

Table 6. Current initiating event data and trend summary.
